# Preface

## What is Covered in This Book

This book describes the theory and operation of the Artix locator service.

## Who Should Read This Book

This book is intended for administrators and developers who want to configure and deploy an Artix locator service.

The information in this book is at an intermediate to advanced level, and presumes the reader has a working knowledge of WSDL contracts, C++, Artix configuration concepts, and the deployment of Artix plug-ins into an Artix container.

## How to Use This Book

This book is organized into the following chapters:

- “[Artix Locator Introduction](#)” provides an overview of the Artix locator and its uses.
- “[Configuring and Deploying the Locator Service](#)” describes how to edit your Artix configuration files to deploy one or more Artix locator services. This chapter also describes how an Artix post-3.x locator can be used by Artix 3.x consumers.
- “[Using the Locator from an Artix Consumer](#)” describes how to code C++ service consumers that take advantage of and that query a deployed Artix locator. This chapter also describes how to migrate consumers-of-locators from Artix 3 to post-Artix 3.
- “[Using the Locator from a Non-Artix Client](#)” describes how an Artix locator service can be used by consumers generated by other SOA systems—for example, .NET and Axis.

## Artix Documentation Library

For information on the organization of the Artix library, the document conventions used, and finding additional resources, see *Using the Artix Library*, available with the Artix documentation at <https://supportline.microfocus.com/productdoc.aspx>.

# Contacting Micro Focus

Our Web site gives up-to-date details of contact numbers and addresses.

## Further Information and Product Support

Additional technical information or advice is available from several sources.

The product support pages contain a considerable amount of additional information, such as:

- The WebSync service, where you can download fixes and documentation updates.
- The Knowledge Base, a large collection of product tips and workarounds.
- Examples and Utilities, including demos and additional product documentation.

To connect, enter <http://www.microfocus.com> in your browser to go to the Micro Focus home page.

### **Note:**

Some information may be available only to customers who have maintenance agreements.

If you obtained this product directly from Micro Focus, contact us as described on the Micro Focus Web site, <http://www.microfocus.com>. If you obtained the product from another source, such as an authorized distributor, contact them for help first. If they are unable to help, contact us.

## Information We Need

However you contact us, please try to include the information below, if you have it. The more information you can give, the better Micro Focus SupportLine can help you. But if you don't know all the answers, or you think some are irrelevant to your problem, please give whatever information you have.

- The name and version number of all products that you think might be causing a problem.
- Your computer make and model.
- Your operating system version number and details of any networking software you are using.
- The amount of memory in your computer.
- The relevant page reference or section in the documentation.
- Your serial number. To find out these numbers, look in the subject line and body of your Electronic Product Delivery Notice email that you received from Micro Focus.

## Contact information

Our Web site gives up-to-date details of contact numbers and addresses.

Additional technical information or advice is available from several sources.

The product support pages contain considerable additional information, including the WebSync service, where you can download fixes and documentation updates. To connect, enter <http://www.microfocus.com> in your browser to go to the Micro Focus home page.

If you are a Micro Focus SupportLine customer, please see your SupportLine Handbook for contact information. You can download it from our Web site or order it in printed form from your sales representative. Support from Micro Focus may be available only to customers who have maintenance agreements.

You may want to check these URLs in particular:

- <http://www.microfocus.com/products/corba/artix.aspx> (trial software download and Micro Focus Community files)
- <https://supportline.microfocus.com/productdoc.aspx> (documentation updates and PDFs)

# Artix Locator Introduction

*The Artix locator service enables consumers to connect to services in a way that is independent of the service location. This chapter provides an overview of the Artix locator service, including its expected use cases, its operation, and its WSDL contract. This chapter also discusses migrating from earlier versions of the Artix locator service.*

## What is the Locator Service?

The Artix locator is a Web service that provides Web service consumers with a mechanism to discover service endpoints at runtime. The locator isolates consumers from knowledge of a service endpoint's physical location. The locator allows service endpoints to advertise their availability to consumers.

## Use cases

The Artix locator service supports the following use cases:

### **Service endpoint repository**

You can use the Artix locator to isolate the consumers of Artix services from having to know the exact network location of each service. Consumers can query the locator for the current location of a service. This allows you to redeploy popular services onto different hardware or different transports without needing to recompile or reconfigure consumers in any way.

### **Service endpoint grouping and organizing**

You can query the locator for its list of currently registered services, and you can filter and organize the results list by service name, port name, portType, binding, or port extensor name. In addition, you can assign services to named groups either in the service WSDL contract or in the Artix configuration file, and can filter the queried service list by group name. This allows you to add structure to the way consumers view the locator service data.

### **Service load balancing**

If you register multiple instances of a service with an Artix locator using the same service name, the locator automatically employs a round-robin or random algorithm to select the service instance whose reference is returned to requesting consumers. This provides you with a lightweight mechanism to distribute the load on popular services without the overhead of setting up a highly available system.

### **Service fault tolerance**

The Artix locator has fault tolerance features between the service endpoints and the locator. The service-side locator plug-in is tolerant of restarts of the locator service, and automatically re-registers its endpoints when the locator restarts. The locator service is tolerant of badly behaved services that do not register their endpoints on shutdown: the locator automatically de-registers the service from the locator in the event of a failure on the service side.

### **High availability locator**

The Artix locator can be configured in a high availability configuration with two or more slave locators coordinating with one master locator. This allows you to distribute many instances of the locator across your service network, all of which share the same reliable repository.

## **How the Locator Works**

The Artix locator service is a standalone service that holds a repository of active service endpoints on your service network. The Artix locator service functionality is implemented as a number of Artix plug-ins. In order to use this functionality, you need participation from consumers, service endpoints, and the central locator service. Therefore, to implement locator functionality on your network, you must enable Artix plug-ins for each of these points on your network, and configure them accordingly. You do not have to write any code to use this functionality. Since the locator service is described by a WSDL contract, you can also choose to use the locator functionality directly in your applications.

### **How the locator works**

You can make your applications locator-aware simply by running an instance of the locator service and changing the configuration of your applications.

Services are made locator-aware by means of configuration statements in the Artix configuration files associated with those services. A locator-aware service automatically registers itself with the locator during service startup. The locator and its registered services periodically confirm that their communication pathways are operational by pinging each other. This monitoring is performed by the peer manager plug-in, which is automatically loaded by the Artix runtime when the locator functionality is enabled.

Consumers are also made locator-aware by means of configuration statements in their associated configuration files. Consumers are required to initialize their proxies in a certain way to take advantage of this functionality. A locator-aware consumer automatically contacts the locator service when it is setting up its proxies. The consumer-side locator plug-in contacts the locator service and provides the QName for the desired service endpoint.

The locator returns a reference, which contains the addressing details needed to invoke the target service. This is passed to the consumer, which then instantiates a proxy to the target service.

The consumer-side locator plug-in performs a simple lookup of service endpoints based on the target service's QName. If a consumer needs to use the more advanced querying operations of the locator service, then such queries need to be coded directly into the consumer.

## The locator and references

Starting with Artix 4.0, the Artix locator returns references using the WS-Addressing standard for Web service references. Previous Artix releases used the proprietary Artix Reference format.

WS-Addressing references are represented by an instance of a class that represents the addressing of the target service endpoint. All proxies in Artix have constructors that take a WS-Addressing reference as a parameter. The reference contains sufficient information to allow the consumer to create a functional proxy to a service endpoint.

## Registering endpoints

An Artix service registers its endpoints with the locator in order to make them accessible to Artix consumers. When a service registers an endpoint in the locator, it creates an entry in the locator's list of services. The entry associates a service QName with a reference for that endpoint.

## Looking up references

An Artix consumer looks up a reference in the locator in order to find an endpoint associated with a particular service. After retrieving the reference from the locator, the consumer can then establish a remote connection to the target service by instantiating a consumer proxy object. This procedure is independent of the type of binding or transport protocol.

Looking up references can be performed on behalf of the consumer by configuring it to use the locator consumer plug-in. As an alternative, you can write lookup code directly using the WSDL interface that the locator service exposes.

## Automatic load balancing

If multiple endpoints are registered against the same service QName in the locator, the locator employs a random or round-robin algorithm to pick one of the endpoints. The locator thereby effectively *load balances* a service over all of its associated endpoints.

For example, an AddNewCustomer service might be listed in an Artix locator with two endpoints registered against it:

- Service: AddNewCustomer  
WSDL location: http://mainhost:2900/service/newcustomer
- Service: AddNewCustomer  
WSDL location: http://backuphost:2900/service/newcustomer

When an Artix consumer looks up a reference for AddNewCustomer, it obtains a reference to whichever endpoint is next in the sequence.

## Locator-related plug-ins

Most of the communication details between the locator, registered services, and consumers are handled by Artix plug-ins. The locator-related plug-ins are:

**Locator service plug-in** (service\_locator) This is the main locator service plug-in. It accepts and tracks service registrations, and hands out service references to requesting consumers.

This plug-in is normally deployed as a standalone service typically using the Artix container. All consumer and service endpoints need to be aware of this shared service on startup.

This plug-in is also responsible for making sure its data is reliable. It removes service endpoints from its repository if it believes they are inactive.

**Locator endpoint manager plug-in** (locator\_endpoint)

This is the portion of the locator that resides with the service endpoints you want registered in the locator service. It registers its service endpoint with the locator service when they become active, and it de-registers them when they are shut down.

This plug-in is also responsible for registering its endpoints with the locator if the locator service is restarted.

**Locator consumer plug-in** (locator\_client)

This plug-in queries the locator service and returns a reference to the target service.

When you load an instance of the `service_locator` or `locator_endpoint` plug-in into an Artix container, the container automatically loads the `peer_manager` plug-in. The `peer_manager` plug-in is responsible for the fault tolerant behavior of the locator service.

The `service_locator` and `locator_endpoint` plug-ins are optionally used alongside the `wSDL_publish` plug-in. The `wSDL_publish` plug-in is strongly recommended when working with the locator.

## How do the plug-ins interact?

In the examples in this book and in locator demonstration code, the **locator service** plug-in is deployed in an Artix container. Although it can be deployed in any Artix process, the recommended approach is to use the container. The Artix container and plug-in architecture is described in “Deploying Services in an Artix Container” in *Configuring and Deploying Artix Solutions, C++ Runtime*.

The locator service plug-in automatically loads the `peer_manager` service, and if specified, the `wSDL_publish` service, into the same Artix container. The container’s URL is published in some way so that other processes can locate the container.

The container process selects a TCP port on which to place the locator service<sup>1</sup> (unless you specify an exact port in configuration). Consumer processes can use the published URL of the container to ask the container to send the locator service’s URL, its WSDL contract, or a reference to the locator.

An Artix service process can be deployed in a standalone server or in another Artix container. For clarity, the examples in this book and in the locator demonstration code show the service deployed in a standalone server. The recommended approach is to use a container when developing your services.

The service process is configured to load the **locator\_endpoint** plug-in. The service’s server executable is started with a command-line directive that identifies the URL, WSDL, or reference of the locator service (as previously obtained from the container housing the locator). Thus, when the service process starts up, its associated `locator_endpoint` plug-in automatically contacts the locator and registers the service.

Thereafter, the `peer_manager` plug-ins associated with both the `locator_service` and `locator_endpoint` plug-ins periodically ping each other to make sure both parties are still active. If either party detects that the other is inactive, action is taken to remedy the situation. For the `locator_service` side, the inactive endpoints are removed; for the `locator_endpoint` side, the plug-in attempts to re-establish communication in case the locator service is restarted.

The **locator\_client** plug-in is loaded into a consumer by means of configuration. This plug-in handles the details of getting a reference to the target service. The consumer uses this reference to create a proxy to the target service.

1. This locator service is usually run on the same port as the container itself. Thus, for example, if you query the container at `localhost:9300`, chances are good the locator service will be found at `localhost:9300` as well.

## Locator service groups

Starting with Artix 4.0, you can assign services to named groups so that a group of related services can be identified by group name when you query the locator. Group assignments can be made in the service's WSDL contract or in an Artix configuration file.

The use of locator service groups is described in [“Service groups” on page 37](#).

## Setting up a locator service

Configuring and running an Artix locator service does not require writing any code. You set up a locator service by means of configuration settings in your Artix configuration file. You start the locator by starting an instance of the Artix container executable that is directed to a locator-specific configuration scope in that configuration file.

The configuration and setup of the Artix locator service is described in [“Configuring and Deploying the Locator Service” on page 13](#).

## Using the locator from consumers

You can configure consumers to make use of the Artix locator with two different approaches:

1. Add the consumer-side locator plug-in to the configuration of consumers, by editing your Artix configuration file. Your consumer-side code will take advantage of this plug-in as long as it uses the standard Artix methods of resolving the initial reference to its target service.
2. Write code that queries the locator directly using the WSDL contract that defines the locator service. Using this method, you can perform simple endpoint lookups as well as advanced querying.

The configuration and coding of locator-enabled consumers is described in [“Using the Locator from an Artix Consumer” on page 29](#).

## Locator WSDL Contract

The Artix locator service is described in the `locator.wsdl` contract, which defines the public interface through which the service can be accessed either locally or remotely. The locator WSDL contract is installed by default to the following location in your Artix installation:

```
ArtixInstallDir/wsdl/locator.wsdl
```

## LocatorService portType

The locator WSDL contract defines a single portType, LocatorService. This portType includes public operations for use by Artix developers, as well as internal operations used to communicate with services as they register and deregister with the locator service.

## Binding and protocol

The locator is accessed through the SOAP binding over the HTTP protocol.

## Public operations

The public operations defined for the LocatorService portType are the following:

- **lookupEndpoint** A request-response operation used by a consumer process to look up an endpoint from the locator based on the target service's QName.
- **listEndpoints** A request-response operation used by a consumer process to list all endpoints registered with the locator.
- **queryEndpoints** A request-response operation used by a consumer process to list all endpoints registered with the locator based on selection filters.

## Internal operations

The following operations defined in `locator.wsdl` are used internally by the `locator_endpoint` plug-in when communicating with the `locator_service` plug-in:

- **registerPeerManager** Register a peer endpoint manager with the locator service. Once registered, the locator associates a peer ID with the peer endpoint manager.
- **deregisterPeerManager** De-register a peer endpoint manager with the locator service. De-registering a peer manager also de-registers all endpoints that were registered by it.
- **registerEndpoint** Register an endpoint to become available in the locator. Once registered, an endpoint is returned in the response to the `listEndpoints` and `queryEndpoints` operations.
- **deregisterEndpoint** De-register an endpoint from the locator. Once deregistered, an endpoint is no longer returned in the response to the `listEndpoints` and `queryEndpoints` operations.

# Locator Sample Code

Artix includes code samples that illustrate various Artix features. Read the `Readme.txt` file in each sample's directory for instructions on building and running that sample.

Five demos illustrate different aspects of the locator as used with the C++ runtime. The locator-related demos for this runtime are installed in subdirectories of:

`ArtixInstallDir/samples/advanced/`

## locator sample

The primary locator sample illustrates how the locator can isolate consumers from knowledge about changes in a service's physical location. Most examples in this manual are simplified versions of this locator sample. This sample shows how you can locator-enable an application simply using configuration. The consumer and server code are not aware that the locator is being used for discovery of endpoints.

## locator\_query sample

The `locator_query` sample illustrates more advanced uses of the locator lookup that the consumer-side plug-in does not implement. It illustrates how to use the `listEndpoints` operation to obtain a list of the services registered with a locator. The sample goes on to illustrate how you can filter the returned list of services with various query selection elements, using the `query_endpoints` operation.

## located\_router sample

The `located_router` sample illustrates how endpoints that are wrapped by an Artix router can still use the locator service for dynamic discovery of endpoint information. In this sample, the endpoints that the router creates are automatically registered with the locator when the router starts up.

## locator\_load\_balancing sample

The `locator_load_balancing` sample demonstrates how the locator can be used to provide load balancing across several server processes hosting the same Web service, without the overhead of setting up a highly available infrastructure.

## high\_availability\_locator sample

The `high_availability_locator` sample illustrates how to run the Artix locator in a replicated and highly-available mode.

# Migrating from Previous Versions

The Artix post-3.x locator service supports queries from unmodified Artix 3.x consumer code. This allows you to migrate at your own pace from an Artix 3.x-based installation to an Artix post-3.x-based installation. You can replace Artix 3.x locators and services with Artix post-3.x locators and services without having to rewrite or change your consumers.

## Backward compatibility

Although the Artix 3.x locator returns references in the proprietary Artix Reference format, the Artix post-3.x locator returns references in WS-Addressing format. To maintain backward compatibility, the Artix post-3.x locator service combines two distinct functionalities—3.x and post-3.x—in a single plug-in. The plug-in enables an Artix 3.x service that supports the locator WSDL from Artix 3.x. It also enables a more advanced Artix post-3.x locator service. As shipped, both services are active, but you can disable the Artix 3.x service if your network does not have Artix 3.x service endpoints or consumers.

As illustrated in [Figure 1](#), Artix 3.x consumers can query an Artix post-3.x locator and get the expected results.

**Figure 1:** *Artix locator backward compatibility*

## Locator service QNames

The QName for the Artix post-3.x locator service is:

```
{http://ws.iona.com/2005/11/locator}LocatorService
```

The QName for the Artix 3.x-compatible locator service that runs alongside the Artix post-3.x locator service is the same as it was for Artix 3.x, which is:

```
{http://ws.iona.com/locator}LocatorService
```

You can verify that both locator services are running in the Artix post-3.x locator by querying the container with the `it_container_admin` command. For example:

1. Go to the Artix 5.x locator demonstration in `ArtixInstallDir/samples/advanced/locator`.
2. Load the Artix C++ environment by invoking the `artix_env[.bat]` command.
3. Build the C++ demo as described in the demo's `Readme.txt` file.

4. From the demo's bin directory, start the locator with the `start_locator` command.
5. From the bin directory, run the following command:

```
it_containter_admin -container ../etc/ContainerService.url  
-listservices
```

6. The following list of service QNames is returned:

```
{http://ws.iona.com/peer_manager}PeerManagerService  
  ACTIVATED  
{http://ws.iona.com/2005/11/locator}LocatorService  
  ACTIVATED  
{http://ws.iona.com/locator}LocatorService ACTIVATED
```

## Supported configurations

The following combinations of Artix services and consumers are supported by the locator service shipped with Artix post-3.x and the locator shipped with the C++/Java JNI runtime of Artix post-3.x:

- Post-3.x services and post-3.x consumers
- Post-3.x services and 3.x consumers
- 3.x services and post-3.x consumers
- 3.x services and 3.x consumers

The terms used here have the following meanings:

Artix post-3.x service Uses the Artix 4.x or 5.x C++ `locator_endpoint` plug-in.

Artix post-3.x consumer Uses the Artix 4.x or 5.x C++ `locator_client` plug-in, or is coded to create a proxy to the locator using the new locator QName.

Artix 3.x service Uses the Artix 3 `locator_endpoint` plug-in.

Artix 3.x consumer Uses no plug-in; is coded to create a proxy to the locator using the old locator QName.

## Unsupported configurations

Neither Artix post-3.x services nor Artix post-3.x consumers (as defined above) work in any combination with a locator service that uses the `locator_service` plug-in shipped with Artix 3.x.

## Migration strategies

The Artix post-3.x locator service is backward compatible by default. There are no configuration steps required to enable backward compatibility in the locator service itself.

Locator services for Artix 4.1, 4.2, and the C++/Java JNI runtime of Artix 5.x require a one-line addition to their Artix configuration files, as described in [“Artix post-3.x locator setup for backward compatibility”](#).

You can start your Artix post-3.x services in a way that supports both Artix 3.x and post-3.x consumers. See [“Starting Services with Artix 3 Consumer Support”](#) on page 23.

You can migrate your consumers one at a time to Artix post-3.x locator compatibility, using the steps described in [“Migrating Consumer Code”](#) on page 40.

## Artix post-3.x locator setup for backward compatibility

The `artix.cfg` file shipped with Artix 4.1, Artix 4.2, and the C++/JAX-RPC runtime of Artix 5.x, all have a configuration entry, `bus:non_compliant_epr_format`. The shipped `artix.cfg` sets this entry by default to `"false"`. This setting allows for greater interoperability between Artix and Web services software from other vendors.

If your site uses a locator service, locator-enabled services, and locator-enabled consumers all built with Artix 4.1, 4.2, or the C++/JAX-RPC runtime of Artix 5.x, then no further configuration is necessary.

If your site uses a locator service built with one of the following:

- Artix 4.1
- Artix 4.2
- Artix 5.x/C++

and your site uses services and consumers built with both of the following:

- Artix post-3.x
- Artix 3.x,

then you must add one configuration entry in your Artix configuration. Add the line to the `locator.service` scope of the configuration file that controls your instance of the locator service. The line to add is:

```
bus:non_compliant_epr_format = "true";
```

**Note:** The locator-related demos that ship with Artix 4.1, Artix 4.2, and Artix 5.0/C++ do not have this line added to their `locator.cfg` files.

For example, the following example shows an edited `locator.cfg` file for the primary locator demo that allows Artix 3.x and post-3.x consumers to connect to and use the Artix 4.1/4.2/5.0-C++ locator service:

```
demo
{
  locator
  {
    client
    {
      orb_plugins = ["xmlfile_log_stream", "locator_client"];
    };

    server
    {
      orb_plugins = ["xmlfile_log_stream", "wsdl_publish",
"locator_endpoint"];
    };

    service
    {
      orb_plugins = ["xmlfile_log_stream", "wsdl_publish",
"service_locator"];
      bus:non_compliant_epr_format = "true";
    };
  };
};
```

## Disabling locator support for Artix 3.x

When you have migrated all Artix consumers to Artix 4.x or 5.x/C++, the backward compatibility feature of the Artix 4.x/5.x-C++ locator is no longer necessary for your site. However, there is no need to disable the backward compatibility feature, and the Artix 4.x/5.x-C++ locator performance is not improved by disabling backward compatibility.

If you prefer to disable this feature anyway, you can use a local configuration scope to override the Artix root configuration. In your local scope, set the WSDL path equal to an empty string for the Artix 3.x-compatible version of the locator service, using a line like the following:

```
bus:qname_alias:locator_oldversion = "";
```

# Configuring and Deploying the Locator Service

*This chapter discusses how to configure and deploy an Artix locator service by editing configuration files.*

## Deploying the Locator Service

The Artix locator service for C++ applications is implemented using Artix plug-ins. This means that any Artix application can host the locator service by loading the `service_locator` plug-in. However, it is recommended that you deploy the locator using the Artix container. This section describes deploying into the Artix container in detail.

### Artix C++ runtime configuration concepts

The information in this section presumes an understanding of Artix C++ runtime configuration concepts and practices, as described in ***Configuring and Deploying Artix Solutions, C++ Runtime***. See the chapters "Artix Configuration" and "Accessing Contracts and References."

## Configuring the locator to run in a container

To configure the locator to run in an Artix container, make sure the `service_locator` plug-in is included in the locator's configuration scope. For example, [Example 1](#) shows the `locator.cfg` file used by the demo in

`ArtixInstallDir/samples/advanced/locator/etc/:`

**Example 1:** *Locator demo's locator.cfg file*

```
include "../../../etc/domains/artix.cfg";
demo
{
  locator
  {
    client
    {
      orb_plugins = ["local_log_stream", "locator_client"];
    };
    server
    {
      orb_plugins = ["local_log_stream", "wsdl_publish",
"locator_endpoint"];
    };
    service
    {0
      orb_plugins = ["local_log_stream", "wsdl_publish", "service_locator"];
    };
  };
};
```

The portion of [Example 1](#) in bold shows a service in the scope `demo.locator.service` configured to load the `wsdl_publish` and `service_locator` plug-ins (as well as a logging plug-in). The `service_locator` plug-in implements the locator service functionality.

The locator service uses SOAP over HTTP, so the `soap` and `at_http` plug-ins are loaded automatically when the process parses the locator's WSDL contract.

## Dynamic port used by default

By default, the locator is configured to deploy on a dynamic port. In the default locator WSDL contract (installed by default in `ArtixInstallDir/wsd\locator.wsdl`), the addressing information is as shown in [Example 2](#):

**Example 2:** *Locator Service on Dynamic Port in default locator.cfg*

```
<service name="LocatorService">
  <port binding="ls:LocatorServiceBinding"
        name="LocatorServicePort">
    <soap:address
      location="http://localhost:0/services/LocatorService"/>
    </port>
  </service>
```

The `localhost:0` port means that when you activate the locator service, the operating system assigns a port dynamically on startup.

The locator service must itself be easily locatable by consumers. Starting the locator on a dynamic port means it would start up on a different TCP port with every restart. This is not useful in a production environment because you need to make sure that all consumers and services on your network can access your locator service. Contacting the locator may be difficult if it starts on a different port every time.

## Configuring a fixed port

There are several ways to deploy the locator on a well-known fixed port:

- You can edit the default `locator.wsdl` contract (this is not recommended).
- You can create a copy of `locator.wsdl` contract for your application and deploy it in a separate configuration scope.
- You can use features of the Artix container to determine the port on which the container deploys the locator.

### Editing the default locator contract

To edit the default `locator.wsdl` contract, perform the following steps:

1. Open the `locator.wsdl` contract in any text editor. By default, this contract is in the following directory:

```
ArtixInstallDir\wsdl\locator.wsdl
```

2. Edit the `soap:address` attribute at the bottom of the contract to specify the desired port in the address. [Example 3](#) shows a modified locator service contract entry. The portion shown in boldface has been modified to point to port 9000 on the local computer.

**Example 3:** *Locator Service on Fixed Port*

```
<service name="LocatorService">
  <port name="LocatorServicePort" binding="ls:LocatorServiceBinding">
    <soap:address location="http://localhost:9000/services/locator/LocatorService" />
  </port>
</service>
```

### Creating a new locator contract

To create a new `locator.wsdl` contract, perform the following steps:

1. Copy the default `locator.wsdl` contract to another location, and open it in any text editor.
2. Edit the `soap:address` attribute at the bottom of the contract to specify the correct address, as shown in [Example 3](#).
3. In your Artix configuration file, in the application's scope, add a new `bus:initial_contract:url:locator` variable that points to your edited WSDL contract. For example:

```
bus:initial_contract:url:locator =
  "/myartix/etc/wsdl/locator.wsdl";
```

The default `bus:initial_contract:url:locator` variable is in the global scope, which ensures that every application has access to the contract. Specifying a new contract in your application scope overrides the global locator contract for your application.

## Configuring a range of ports

You can also limit the range of ports that the locator is deployed on (that is, the range of ports for the locator's SOAP or HTTP address). To do this, specify the range of ports in the `artix.cfg` file, as shown in [Example 4](#).

**Example 4:** *Locator Port Range*

```
policies:http:server_address_mode_policy:port_range="12345:12349";
```

In [Example 4](#), the desired range of ports is highlighted.

When the locator has been correctly configured, it can be started like any other application. The only difference is that the locator service must be started before any applications that need to use it.

## Deploying the locator in the container

The recommended deployment for the locator is in an instance of the Artix container. To deploy the default locator in the container, perform the following steps:

1. Run the locator in the Artix container, for example:

```
it_container -ORBname demo.locator.service
             -ORBdomain_name locator -ORBconfig_domains_dir
             /myartix/etc -publish
```

2. Query the container with the `it_container_admin` command (or with your own code). Ask the container to publish the live version of the locator WSDL after the container has assigned a port for the locator. For example:

```
it_container_admin
  -container /myartix/etc/ContainerService.url
  -publishwsdl
  -service
  {http://ws.iona.com/2005/11/locator}LocatorService
  -file /myartix/etc/locator-activated.wsdl
```

This retrieves the locator's activated WSDL contract. This is the contract in which the default WSDL's port 0 has been dynamically updated with the actual port that the service is using. In this example, `it_container_admin` writes the contract to the `locator-activated.wsdl` file in the `/myartix/etc` subdirectory.

3. Finally, you must make sure your consumers use the activated WSDL file, now resident in the specified directory, when each consumer starts up at runtime.

## Deploying the locator in the container on a fixed port

As an alternative, you can use the `-port` option when starting the container to specify that the container runs a service on a fixed port. For example:

```
it_container -port 9000 -ORBname demo.locator.service
             -ORBdomain_name locator -ORBconfig_domains_dir /myartix/etc
             -publish
```

In this example, any services that run in the container, and have default contracts with a port of 0, will now use port 9000.

You can manually update the WSDL used by your consumer to 9000, or you can publish the WSDL from the container using `it_container_admin` with the `-publishwsdl` option, shown in ["Deploying the locator in the container"](#).

## Shutting down the locator

To shut down a locator running in a container, use the container's shutdown option. For example:

```
it_container_admin -ORBdomain_name locator
                  -ORBconfig_domains_dir /myartix/etc -container
                  /myartix/etc/ContainerService.url -shutdown
```

or if you deploy the locator and container on a fixed port:

```
it_container_admin -ORBdomain_name locator -host artixserver
                  -port 9000 -shutdown
```

## Further information

The Artix container and plug-in architecture is discussed in more detail in "Deploying Services in an Artix Container" in *Configuring and Deploying Artix Solutions, C++ Runtime*.

## Registering Services with the Locator

A service does not need to have its implementation changed to work with the Artix locator. The only requirements are that the service is configured to load the correct plug-ins, and to reference the correct locator contract.

If you require more fine-grained control, you can control the service endpoints that are registered. You may want to do this if you have some services that you do not want to be visible to consumers.

Whichever Artix runtime you use, you locator-enable services by means of configuration, not coding.

## Configuring a Locator-Enabled Service, C++ Runtime

Any service that wishes to register itself with the locator must load the `locator_endpoint` plug-in. The `locator_endpoint` plug-in enables the service to register with the running locator. The following example shows the configuration scope of a service that registers with the locator service.

```
my_service
{
    orb_plugins = ["xmlfile_log_stream", "wsdl_publish",
                  "locator_endpoint"];
};
```

Another example is shown in [Example 1 on page 14](#), where a service in the scope `demo.locator.service` is configured to load the `locator_endpoint` plug-in.

## Using a copy of locator.wSDL

If you are using a copy of the default locator contract to specify a fixed port, the service configuration must also specify the location of the contract. For example:

```
bus:initial_contract:url:locator="/opt/local/my_service/locator.wSDL";
```

This is not necessary if you are using a dynamic port, or have overridden the default contract in a configuration scope with a fixed port. The global `bus:initial_contract:url:locator` setting is used instead.

For more information, see the *Artix Configuration Reference, C++ Runtime*.

## Filtering service endpoints

By default, any service activated in an Artix bus that loads the `locator_endpoint` plug-in is automatically registered in the locator.

However, you may not want every service registered or exposed to the locator. Artix allows you to filter the endpoints that are registered by the locator endpoint manager. You can do this by explicitly including or excluding endpoints using configuration variables.

Configuration variables are discussed in detail in *Configuring and Deploying Artix Solutions, C++ Runtime*.

## Excluding endpoints to be registered

If there are a small number of endpoints that you want to be filtered out, you can explicitly exclude those endpoints from the locator by using the `exclude_endpoints` configuration variable.

For example, if you do not want to register the container service, but want to register all the endpoints that are activated in that container, use the following setting:

```
plugins:locator_endpoint:exclude_endpoints =  
  [{"http://ws.iona.com/container}ContainerService"];
```

For an example of this configuration, see the `located_router` demo.

## Including endpoints to be registered

If you have a small number of endpoints that you want to be added, and want to filter out all others, you can use the `include_endpoints` configuration variable.

For example, if you only want to register the session manager, but not any of the endpoints that it manages, use the following setting:

```
plugins:locator_endpoint:include_endpoints =
  [{"http://ws.iona.com/sessionmanager}SessionManagerService"];
```

**Note:** Combining the `exclude_endpoints` and `include_endpoints` configuration variables is ambiguous and unsupported. If you do this, the application fails to initialize.

## Filtering endpoints using wildcards

You can use wildcarded service names with endpoint-filtering configuration variables. This enables you to filter based on a specified namespace.

You can specify that all services defined in a particular namespace should be included. For example:

```
plugins:locator_endpoint:include_endpoints =
  [{"http://www.example.com/finance}*"];
```

Alternatively, you can use the following setting to exclude all services defined in a particular namespace:

```
plugins:locator_endpoint:exclude_endpoints =
  [{"http://www.example.com/finance}*"];
```

## Service registration

When a properly configured service starts up, it automatically registers with the locator specified by the contract pointed to by `bus:initial_contract:url:locator`.

You can register multiple instances of the same service with a locator. These service instances must be running in different applications (buses). When the locator receives multiple registrations of the same service implemented in different server applications, the locator generates a pool of references for the service type. When consumers make a request for a service, the locator supplies references from this pool using a load-balancing algorithm. For more information on load balancing see [“Using Load Balancing” on page 20](#).

## Using Load Balancing

The Artix locator provides a lightweight mechanism for balancing workloads among a group of services. When several services with the same service name register with the Artix locator, it automatically creates a list of references to each instance of this service. The locator hands out references to consumers using a round-robin or random algorithm. This process is automatic and invisible to both consumers and services.

## Starting to load balance

When the locator is deployed and your services are properly configured, you must bring up a number of instances of the same service. This can be accomplished by one of the following methods, depending on your system topology:

- Start multiple services using the same WSDL contract but without hard coding the addressing for that service. For example, if the service uses HTTP, use a location such as `location=http://servicehost:0/serviceName`. If the service uses CORBA, use the address `location="IOR:"`.
- Create a number of copies of the WSDL contract defining the service, and change the addressing information so that each copy has a unique address. Then bring up each service instance using a different copy of the contract.

**Note:** The locator determines whether a service is part of a group by using the name specified in the `service` element of the service's contract. If you are using the Artix locator to load balance, each instance of your service should be associated with the same binding and logical interface. Otherwise, consumers might end up using a different binding, transport, or portType, depending on the endpoint reference obtained from the locator service.

As each service starts up, it automatically registers with the locator. The locator recognizes that the services all have the same service name specified in their Artix contracts and creates a list of references for these service instances.

As consumers make requests for the service, the locator cycles through the list of server instances to hand out references.

## Using Fault Tolerance Features

Enterprise deployments demand that applications can cleanly recover from occasional failures. The Artix locator is designed to recover from the two most common failures faced by a look-up service:

- Failure of a registered endpoint.
- Failure of the look-up service.

### Endpoint failure

When an endpoint gracefully shuts down, the `locator_endpoint` plug-in associated with that endpoint notifies the locator that it is no longer available. The locator removes the endpoint from its list so it cannot give a consumer a reference to a dead endpoint.

However, when an endpoint fails unexpectedly, it cannot notify the locator, and the locator can unknowingly give a consumer an invalid reference. This might cause the failure to cascade onto one or more consumers if consumers try to invoke on a dead endpoint.

To decrease the risk of passing invalid references to consumers, the locator service monitors the health of the endpoints that have been registered with it. If it determines that an endpoint is no longer available, it removes that endpoint from its database. The locator service can determine the availability of its registered endpoints because it expects those endpoints to send periodic ping messages to the locator service. If these messages stop arriving, the locator service determines that the endpoint is dead.

You can adjust the interval between locator service pings by setting the `plugins:locator:peer_timeout` configuration variable. The default and minimum setting is 10,000 milliseconds (10 seconds). For further information on this configuration variable, see the ***Artix Configuration Reference, C++ Runtime***.

## Locator service failure

If the locator service itself fails, and it is not running in high availability mode, all the references to the registered endpoints are lost, and the active endpoints are no longer registered with the locator. The endpoints detect when the locator service fails, because they are expecting periodic messages from the locator using the peer manager service. Once an endpoint determines that the locator has failed, it attempts to reconnect to the locator and reregister its endpoints. This behavior lets you stop and restart a deployed locator service without interruption to the consumers and services on the network.

You can adjust the interval with which the locator pings the endpoints by setting the `plugins:locator:peer_timeout` configuration variable. The default and minimum setting is 10,000 milliseconds (10 seconds). For further information on this configuration variable, see the ***Artix Configuration Reference, C++ Runtime***.

## Highly available locator cluster

You can configure three or more instances of the locator service in a highly available locator cluster. This configuration is illustrated in the `high_availability_locator` demo.

The setup and configuration of a high availability locator cluster is discussed in the “Deploying High Availability” chapter of ***Configuring and Deploying Artix Solutions, C++ Runtime***. See especially the “Configuring Locator High Availability” section of this chapter.

# Starting Services with Artix 3 Consumer Support

This section describes how to start Artix post-3.x services in a way that supports both Artix 3.x and post-3.x consumers.

## Migrating Artix post-3.x services

There are no required changes to your application code between Artix 3.x and Artix post-3.x for locator-aware Artix services. You can migrate your service and application code from Artix 3.x to Artix post-3.x with these steps:

- Regenerate stub code generated from WSDL using the Artix post-3.x code generators.
- Recompile and link your service application.
- Make sure the Artix post-3.x version of the `locator_endpoint` plug-in is loaded at runtime and is configured correctly.
- To allow Artix 3.x and post-3.x consumers to connect to an Artix post-3.x locator service, add one configuration line to the locator service configuration scope, as described in [“Artix post-3.x locator setup for backward compatibility” on page 11](#).

## Specify the right QName

As described in [“Locator service QNames” on page 9](#), the Artix post-3.x locator implements both Artix 3.x and post-3.x-compatible locator services. If you access an Artix post-3.x locator using the QName of the Artix 3.x locator, then the Artix post-3.x locator responds as an Artix 3 locator.

## Supporting Artix 3 consumers

To support Artix 3 consumers from your Artix post-3.x services, you must:

- Run your locator service using the Artix post-3.x version of the `locator_service` plug-in.
- Make sure the Artix 3-compatible WSDL published from the Artix post-3.x locator is accessible to your Artix 3 consumers resides in the location they expect.

Supporting the last bullet point depends on how you implemented the port on which the locator runs:

- By assigning a fixed port number
- By retrieving the activated WSDL from the locator and storing it in a location accessible to consumers

## Artix 3 interoperability if the locator is on a fixed port

The locator demos `located_router` and `locator_load_balancing` use the fixed port method. Both demos use a copy of `locator.wsdl` that assigns port 9000. This was true in both Artix 3.x and Artix post-3.x versions of the demo code.

Consumers of the Artix 3 demo should be able to locate and use the services of the Artix post-3.x demo without any changes. This is because the Artix post-3.x locator will run on port 9000, and the Artix 3 consumers will look for the locator on port 9000. The Artix 3 consumers will make requests using the Artix 3 QName of the locator service. This invokes the Artix 3 compatibility of the Artix post-3.x locator running at port 9000.

If your own consumers use a fixed port for the locator service, then Artix 3 consumers should run without any changes against the Artix post-3.x locator service running on the same port.

## Artix 3 interoperability if you used activated WSDL

The locator demo named `locator` has a script that starts a service. This script queries the locator's container for the locator's WSDL contract, and then writes that activated WSDL to a file. The consumer startup script then reads the activated WSDL from the same file.

You do not need to write the activated locator WSDL to a file at the same time the service starts up, as is done in the `locator` demo. This could occur in a separate script, and only needs to be done once.

If your application uses the technique of writing activated WSDL to a file, then you must modify the script that writes the WSDL. In your modified script, have the WSDL for both Artix 3 and Artix post-3.x locator services written to different network-accessible locations. Remember to write the Artix 3-compatible WSDL to the location your Artix 3 consumers expect to find it.

For example, consumers of the Artix 3 locator demo can be made to interoperate with the locator and services of the same-named Artix post-3.x demo by following these steps. This example uses the Windows version of Artix.

1. This example presumes two Artix installations on the same machine. For example purposes only, let's say that:
  - ◆ Artix post-3.x is installed in `C:\MICROFOCUS`
  - ◆ Artix 3 is installed in `C:\MICROFOCUS3`
2. In the `bin` directory of the Artix post-3.x version of the demo, copy `run_cxx_server.bat` to a new file. Let's call it `4-3_interop.bat`.
3. Add one extra line to `4-3_interop.bat`, as described and shown below.
4. Create a new `4-3_servers.bat` that calls `4-3_interop.bat` five times with five arguments, in the same way that `run_cxx_servers.bat` does.

5. Open a command prompt window and run the test batch files in the following sequence:

```
Run start_locator.bat  
Run 4-3_servers.bat  
Run run_cxx_client.bat  
Run run_dotnet_client.bat
```

6. Open a second command prompt window and change to the Artix 3 locator demo's bin directory.

7. In command prompt window 2:

```
Run run_cxx_client.bat  
Run run_dotnet_client.bat
```

The line you must add to 4-3\_interop.bat runs `it_container_admin` a second time, requesting WSDL using the old locator's QName:

```
-service {http://ws.iona.com/locator}LocatorService
```

Another argument writes the resulting WSDL to the location that the Artix 3 locator demo expects to find and use it:

```
-file /microfocus3/artix/3.0/demos/advanced/locator/etc/locator-activated.wsdl
```

The 4-3\_interop.bat file now looks like the following example. The newly added line is highlighted in boldface.

**Example 5:** Example 4-3\_interop.bat file

```
@echo off
@setlocal
call "../../../../../bin/artix_env.bat";

IF "%1"=="blocking" (
SET DEMO_START=
SHIFT /1
) ELSE (
SET DEMO_START=start
)

IF "%1"=="corba" (GOTO runserver)
IF "%1"=="soaphttp" (GOTO runserver)
IF "%1"=="soaptunnel" (GOTO runserver)
IF "%1"=="fixedhttp" (GOTO runserver)
IF "%1"=="fixedtunnel" (GOTO runserver)

echo valid transports are corba soaphttp soaptunnel fixedhttp
fixedtunnel
GOTO :end

:runserver
cd ..\cxx\server
it_container_admin -container ../../etc/ContainerService.url
-publishwsdl -service
{http://ws.iona.com/2005/11/locator}LocatorService -file
..\..\etc\locator-activated.wsdl

it_container_admin -container ../../etc/ContainerService.url
-publishwsdl -service {http://ws.iona.com/locator}LocatorService
-file
/microfocus3/artix/3.0/demos/advanced/locator/etc/locator-activated
.wsdl

%DEMO_START% server.exe %1 -ORBname demo.locator.server
-ORBdomain_name locator -ORBconfig_domains_dir ../../etc
-BUSservice_contract ../../etc/locator-activated.wsdl

GOTO end

:end
@endlocal
```

## Adding SOAP 1.2 Support

The default locator.wsdl file shipped with Artix contains a SOAP 1.1 binding and a SOAP 1.1 service. Starting with release 4.1, Artix supports SOAP 1.2 bindings as well.

If your site requires the use of SOAP 1.2 bindings for communication with the locator service, follow these steps:

- Make a copy of the default locator.wsdl file.

- Edit your copy to include a SOAP 1.2 binding. See the SOAP 1.2 chapter of *Writing Artix Contracts* for guidelines on adding a SOAP 1.2 binding.
- Use the `bus:initial_contract:url` configuration variable to point to the location of your edited `locator.wsdl` file, or use one of several WSDL publishing methods described in “Accessing WSDL Contracts” in *Configuring and Deploying Artix Solutions, C++ Runtime*.

## SOAP 1.2 considerations

The SOAP 1.2 binding in Artix 4.1, 4.2, and 5.0-C++ supports endpoint references (EPRs) only in the format defined by the WS-Addressing standard, and no longer supports the deprecated proprietary Artix references. Artix’s SOAP 1.1 binding supports both EPRs and the Artix references used by Artix 3.0 and earlier.

This means that an Artix 4.1/4.2/5.0-C++ locator that uses the SOAP 1.2 binding cannot support connections from Artix post-3.x and 3.x consumers, because those Artix versions did not support SOAP 1.2. Thus, when defining your Artix 4.1/4.2/5.0-C++ locator service, if your site intends to maintain backward compatibility with Artix post-3.x and Artix 3.0 consumers, do not also use a SOAP 1.2 binding. The configuration step described in [“Artix post-3.x locator setup for backward compatibility” on page 11](#) is not compatible with a SOAP 1.2 binding.

# Using the Locator from an Artix Consumer

*This chapter describes the configuration and programming steps to enable an Artix consumer to make use of a deployed Artix locator service.*

## Configuring Artix Consumers to Use the Locator Service

Before a consumer can use the Artix locator service, it must be configured to load the required plug-ins. The plug-ins provide native access to the locator service and eliminates the need for creating a proxy to obtain service references.

## Configuring C++ Consumers

This section describes how to configure consumers to use the `locator_client` plug-in, and describes the features of this plug-in.

### Artix configuration concepts

The information in this section presumes an understanding of Artix configuration concepts and practices, as described in *Configuring and Deploying Artix Solutions, C++ Runtime*. See the chapters "Artix Configuration" and "Accessing Contracts and References."

### Configuring a consumer

To use a deployed locator service, configure consumers to load the `locator_client` plug-in.

An example is shown in [Example 1 on page 14](#), where consumers in the scope `demo.locator.client` are configured to load the `locator_client` plug-in. The relevant portion of that example is shown here:

```
demo
{
  locator
  {
    client
    {
      orb_plugins = ["xmlfile_log_stream", "locator_client"];
    };
  };
};
```

Artix releases prior to 4.0 did not use the `locator_client` plug-in, or any plug-in, for consumers of the locator.

**Note:** The `locator_client` plug-in is only supported for interacting with a locator service that uses the Artix post-3.x version of the `locator_service` plug-in. It does *not* query a locator service that uses the Artix 3.x version of the `locator_service` plug-in.

## Consumer plug-in features

The `locator_client` plug-in is responsible for helping consumers to resolve their target service endpoints using the locator service, without having any code that explicitly does so. With the plug-in configured to be used, when the consumer's code attempts to resolve its target service's endpoint, the plug-in connects to the locator service to obtain a reference to the target service. This interaction is triggered by the call to resolve the initial reference to the target service. However, it is the plug-in that implements the actions initiated by that call.

In order to function, the `locator_client` plug-in requires addressing information for the locator service. This can be specified using various techniques outlined in the "Accessing Contracts and References" chapter of [Configuring and Deploying Artix Solutions, C++ Runtime](#). For example, you can pass in the location of the WSDL through the command line, or you can configure the location in the consumer's configuration domain.

There are no configuration variables for the `locator_client` plug-in.

## Obtaining Service References from the Locator Service

Once a consumer is configured to load the locator service plug-ins, it requires some additional coding to use the locator service to obtain references to the services in which it is interested. Each of the programming models supported by Artix has a slightly different way of enabling a consumer's use of the locator service. However, all of the models make it extremely simple.

## Implementing a C++ Consumer

This section shows how to write consumer code in C++ that uses an Artix locator service to locate and connect to a target service of interest.

## C++ consumer code

The steps each locator consumer must take are:

1. Invoke `IT_Bus::Bus::resolve_initial_reference()` on the target service's QName.
2. Using the returned reference, invoke `IT_Bus::ClientProxyBase()` to set up a proxy to the target service.

The `locator_client` plug-in does all the work behind the scenes of connecting to the locator service to obtain a reference to the target service.

**Note:** Locator code in Artix 3 consumers must interact with the locator service using the WSDL contract defining the locator. Locator code in Artix post-3.x consumers no longer has to do this.

## C++ Example

The locator consumer in [Example 6](#) is a small, complete application designed to work in the context of the locator demonstration in `ArtixInstallDir/samples/advanced/locator`.

See ["Explanation of Example 6" on page 33](#) for notes on this example.

**Example 6:** *Locator consumer example in C++*

```
//
// C++ locator example client code
//
#include <it_bus/bus.h>
#include <it_bus/exception.h>
#include <it_cal/iostream.h>
#include "SimpleServiceConsumer.h"

IT_USING_NAMESPACE_STD
using namespace SimpleServiceNS;
using namespace IT_Bus;
using namespace WS_Addressings;

int main(int argc, char* argv[])
{
    cout << endl << "SimpleService C++ Client";

    // Initialize the Artix bus.
    IT_Bus::Bus_var bus;
    try
    {
        cout << endl << "Initializing the bus.";
        bus = IT_Bus::init(argc, (char **)argv,
                          "demo.locator.client");
    }
}
```

**Example 6:** *Locator consumer example in C++ (Continued)*

```
catch (IT_Bus::Exception& err)
{
    cout << endl << "Caught unexpected exception while "
        << "initializing the bus: "
        << endl << err.message() << endl;
    return -1;
}
2 QName service_qname("", "SOAPHTTPService",
    "http://www.iona.com/FixedBinding");

try
{
3 // Get a WS-A reference to the target service.
  EndpointReferenceType ep_ref;
  cout << endl << "Resolving "
      << service_qname.get_local_part()
      << " service in the locator.";
4 if (!bus->resolve_initial_reference(
    service_qname, ep_ref))
    {
        cout << endl
            << "Unable to resolve a reference using "
            << "the locator resolver." << endl;
        return -1;
    }
    // Construct a new proxy to the target service
    // with the result from the locator.
    cout << endl << "Initializing a proxy with the "
        << "results from the locator.";

5 SimpleServiceClient simple_client(ep_ref);

    // Use the new proxy to invoke the say_hello operation
on // the target service.
    cout << endl << "Invoking say_hello on the service "
        << service_qname.get_local_part() << ".";
    String my_greeting = String("Greetings from ") +
        service_qname.get_local_part();
    String result;
6 simple_client.say_hello(my_greeting, result);

    cout << endl << "The say_hello operation returned: "
        << endl << "    " << result << "!";
}

catch (IT_Bus::Exception& err)
{
    cout << endl
        << "Caught unexpected exception while invoking "
        << "on the endpoint: "
        << endl << err.message() << endl;
    return -1;
}
cout << endl << endl;
return 0;
}
```

## Explanation of Example 6

The following points refer to the number labels in [Example 6](#).

1. This example hard codes an association with the `demo.locator.client` configuration scope by means of an argument to the `IT_Bus::init()` call. In a production application, you are more likely to specify the scope in an `-ORBname` parameter when invoking the consumer executable. The association with the configuration scope is what ensures that the `locator_client` plug-in is loaded at runtime. This example presumes a configuration file like the one shown in [Example 1 on page 14](#).
2. This line constructs a QName for the target service to which this consumer will connect at runtime. The components of the QName are defined in the target service's WSDL contract. In this case, the target service's contract is in `ArtixInstallDir/samples/advanced/locator/etc/simple_service.wsdl`.
3. The reference is declared as an instance of the WS-Addressing standard's `EndpointReferenceType`.
4. This line invokes `resolve_initial_reference()`, passing the QName of the target service and an instance of the endpoint reference class.
5. The `SimpleServiceClient` class is defined in the locator demo in `ArtixInstallDir/samples/advanced/locator/cxx/client`. This class is derived from `IT_Bus::ClientProxyBase()`, which is the base class for all Artix C++ proxies. In this case, the proxy is set up for the target service defined in the QName set up as described in paragraph 2 above.
6. Now that the client proxy to the target service is established, the code can invoke operations of the target service. The `say_hello` operation is defined in the target service's WSDL contract, `simple_service.wsdl`.

## Compiling and running Example 6

The code in [Example 6](#) can be saved to a file, then compiled and run in the context of the locator demo, as follows:

- Save the code to a file in `ArtixInstallDir//samples/advanced/locator/cxx/client`.
- Create a separate make file based on the `Makefile` in that directory. Name the output executable something other than `client.exe`.
- Invoke `nmake -f yourmakefile`. (Windows) or `make -f yourmakefile` (UNIX).
- Create a batch file or shell script to run your executable, based on the `run_cxx_client.bat` in the demo's `bin` directory.
- Start the locator demo with `start_locator.bat`.
- Start the example services with `run_cxx_servers.bat`.
- Run the example's batch file or shell script.

When invoked as above, the example code produces output like the following:

```
SimpleService C++ Client
Initializing the bus.
Resolving SOAPHTTPService service in the locator.
Initializing a proxy with the results from the locator.
Invoking say_hello on the service SOAPHTTPService.
The say_hello operation returned:
    Greetings from SOAPHTTPService!
```

## Querying a Locator Service

Starting with Artix post-3.x, the locator has extended query functionality, compared to the basic `listEndpoints` operation offered in prior releases. The locator query capabilities are implemented as the `queryEndpoints` operation, which uses as its input parameter a `select` element defined in an extensible XML schema, `locator-query.xsd`.

### Demonstration code

The querying functionality of the Artix post-3.x locator is illustrated in the `locator_query` demonstration example. See `ArtixInstallDir/samples/advanced/locator_query`.

### Filtered and unfiltered lists of services

To use the query functionality, follow these overall steps in your consumer code:

1. Obtain a reference to the locator service and create a client proxy to the locator.
2. To obtain an unfiltered list of the services registered with that locator, invoke the locator's `listEndpoints` operation.
3. To obtain a filtered list of registered services, invoke the locator's `queryEndpoints` operation, passing it one or more query filters.

### Extensible query language

The query language used by the `queryEndpoints` operation is governed by an XML Schema, which is installed by default in `ArtixInstallDir/schemas/locator-query.xsd`.

The C++ data types used in the examples in this section are from code generated from this schema (or from `locator.wsdl`, which includes this schema). Artix does not ship with code generated from this schema or WSDL, so it is the Artix developer's responsibility to generate code from the schema or WSDL and make use of it.

Because the query language is in a schema, you can extend the schema to add new query functionality.

The contents of the `locator_query.xsd` schema are shown in [Example 7](#).

**Example 7:** *Contents of `locator-query.xsd`*

```
<?xml version="1.0" encoding="UTF-8"?>
<xs:schema
  targetNamespace="http://ws.iona.com/2005/11/locator/query"
  elementFormDefault="qualified"
  xmlns:xs="http://www.w3.org/2001/XMLSchema"
  xmlns:tns="http://ws.iona.com/2005/11/locator/query">
  <xs:simpleType name="FieldEnumeratedType">
    <xs:restriction base="xs:string">
      <xs:enumeration value="GROUP"/>
      <xs:enumeration value="SERVICE"/>
      <xs:enumeration value="PORTNAME"/>
      <xs:enumeration value="INTERFACE"/>
      <xs:enumeration value="BINDING"/>
      <xs:enumeration value="EXTENSOR"/>
    </xs:restriction>
  </xs:simpleType>
  <xs:simpleType name="FilterFieldType">
    <xs:union memberTypes="tns:FieldEnumeratedType xs:string"/>
  </xs:simpleType>
  <xs:complexType name="FilterType">
    <xs:simpleContent>
      <xs:extension base="xs:string">
        <xs:attribute name="field" type="tns:FilterFieldType"
          use="required"/>
      </xs:extension>
    </xs:simpleContent>
  </xs:complexType>
  <xs:complexType name="QuerySelectType">
    <xs:sequence>
      <xs:element name="filter" type="tns:FilterType"
        minOccurs="0"
        maxOccurs="unbounded"/>
      <xs:any namespace="##other" minOccurs="0"
        processContents="lax"/>
    </xs:sequence>
  </xs:complexType>
  <xs:element name="select" type="tns:QuerySelectType"/>
</xs:schema>
```

## Query functionality

The target namespace of the `locator-query.xsd` schema is `http://ws.iona.com/2005/11/locator/query`. The `query:select` element of type `query:QuerySelectType` is a sequence of filters. It is extensible insofar as it can support future `xs:any` elements without breaking compatibility. In the current implementation, the locator service ignores all `xs:any` elements that may be present within a `select` element.

A filter is a pair of *type* and *value*. The *value* is a string; some filters use QName values represented as strings in canonical form:

```
[{<namespace>}]<local-part>
```

The logic to convert QNames to and from canonical string representation is available from the `IT_Bus::QName` type (as shown in the example in this section).

The *type* of a filter is one of the `query:FieldEnumeratedType` values. The filter type is extensible by allowing any other field type. Extensibility was achieved by making the Filter *type* a union of the supported enumerated type and a string. Any value different from the ones present in the enumerated type is ignored by the current locator implementation.

The value of a filter could be either a string or a QName, depending on the filter type. When the value is a QName, you still need to pass it as a string using its canonical value.

The matching rules for the supported filter types are shown in the following table. There is no wildcard support in these filter types, so the search text must be exact.

Filter type	Format	Filter the returned list of services by:
GROUP	<code>xs:string</code>	The case sensitive name of a group of services you are seeking. (Service group membership is defined in each service's WSDL contract or in an Artix configuration file as described in <a href="#">"Service groups" on page 37.</a> )
SERVICE	<code>xs:QName</code>	The QName of the service you are seeking.
PORTNAME	<code>xs:string</code>	The case sensitive name of at least one of the ports in the service you are seeking.
INTERFACE	<code>xs:QName</code>	The QName of the <code>portType</code> associated with a binding, which is itself associated with at least one of the ports in the service you are seeking.
BINDING	<code>xs:string</code>	The QName of the binding associated with at least one of the ports in the service you are seeking.
EXTENSOR	<code>xs:string</code>	The QName of an extensor contained in at least one of the ports in the service you are seeking.

## Service groups

Starting with Artix post-3.x, you can assign arbitrary group membership to services. This feature is used in combination with the locator's query functionality. For example, you could query the locator to ascertain which services belong to which groups.

There is no restriction on assigning services to groups in different processes. It is valid to have services in the same process belong to different groups, or to no group at all. It is valid for services in different processes to belong to the same group. By default, a service belongs to no group.

A service can be assigned to a group by means of a WSDL extension or by means of configuration.

## Assigning group membership with a configuration variable

The preferred method of assigning services to groups is performed in an Artix configuration file, using the `service_group` configuration variable.

Using the QName alias for a service in the configuration file, specify the `service_group` variable and assign an arbitrary string as the group name.

In the following example, the first line defines the QName alias `corba_svc`. The second line assigns the `corba_svc` service to the group named `CORBAGroup`.

```
bus:qname_alias:corba_svc =  
    "{http://demo.iona.com/advanced/LocatorQuery}CORBASvc";  
...  
plugins:locator:service_group:corba_svc = "CORBAGroup";
```

**Note:** Configuration-assigned group membership takes precedence over WSDL-assigned group membership.

You can define a global group for all services associated with the current bus. All services that do not have a group definition in their WSDL or configuration then belong to the global group by default.

```
plugins:locator:service_group = "<default-group-name>";
```

## Assigning group membership in WSDL

You can use an Artix WSDL extension to assign a service to a group in the service's WSDL contract.

The WSDL extension is defined in a new schema under the `types` section in `locator.wsdl`:

```
<xs:schema
  targetNamespace="http://ws.ionas.com/2005/11/locator/extensions"
  >
  <xs:element name="group" type="xs:string"/>
</xs:schema>
```

This allows service WSDL contracts to use the `name=` attribute, as shown in this example taken from the `locator_query` demo.

```
xmlns:locx="http://ws.ionas.com/2005/11/locator/extensions"
...
<service name="CORBAService">
  <locx:group>QUERY-DEMO</locx:group>
  <port binding="tns:SimpleServicePortType_CORBABinding"
    name="CORBAPort">
    <corba:address location="file:../../corba_server.ior"/>
    <corba:policy poaname="corbaport"/>
  </port>
</service>
```

## Locator query example with single query

The following C++ code fragment demonstrates the locator's query functionality. This example uses a single query filter:

```
// Create a query
QuerySelectType select;
FilterType filter;
FilterFieldType fld;

fld.setFieldEnumeratedType(
  FieldEnumeratedType(FieldEnumeratedType::GROUP));
filter.setfield(fld);
filter.setvalue("SAMPLE-VALUE");
select.getfilter().push_back(filter);

// Create a proxy for the locator.
// (This assumes that the bus already been initialized)
Reference locator_ref;
bus->resolve_initial_reference(LOCATOR_SERVICE_NAME,
                              locator_ref);
LocatorServiceClient locator_client(locator_ref);

// Invoke
ElementListT<endpoint> result;
locator_client->queryEndpoints(select, result);

// Use the result in some way ...
```

## Locator query example with multiple queries

The locator supports queries based on multiple filters. The filters restrict the endpoints in the result set to those endpoints that match the value in each filter. They act as a composite filter with an implicit AND operator.

Filters have a type and a value. There are no restrictions on mixing different filters based on their type. It is valid to add filters of the same type.

The following C++ code fragment illustrates the use of the locator's query functionality with multiple query filters.

```
QName sample_portType("", "MyPortType",
    "http://www.example.com/demo");

QuerySelectType select;
FilterType filter;
FilterFieldType fld;

fld.setFieldEnumeratedType(
    FieldEnumeratedType(FieldEnumeratedType::GROUP));
filter.setfield(fld);
filter.setvalue("SAMPLE-VALUE");
select.getfilter().push_back(filter);

fld.setFieldEnumeratedType(
    FieldEnumeratedType(FieldEnumeratedType::INTERFACE));
filter.setfield(fld);
filter.setvalue(sample_portType.get_as_canonical_string());
select.getfilter().push_back(filter);
```

## Migrating Consumer Code

The following differences between Artix 4.x/5.x-C++ and Artix 3.0 might affect any existing Artix consumers:

- Locator WSDL operation names were changed in compliance with the wrapped doc-literal convention.
- Artix switched from using a proprietary reference format to using the standard WS-Addressing endpoint reference format.
- Locator consumers are now configured to load the `locator_client` plug-in. This plug-in takes over the tasks of creating a proxy to the target service. These tasks were formerly the responsibility of consumer code.

For WS-Addressing migration information, see the chapters "Endpoint References" in *Developing Artix Applications in C++*.

## Old and new locator WSDL contracts supported

As described in [“Backward compatibility” on page 9](#), the Artix post-3.x locator service incorporates both Artix 3.x and post-3.x-compatible locator services.

Artix post-3.x includes a newer version of `locator.wsdl`. The new `locator.wsdl` file is located by default in the following directory of your Artix installation:

### Artix 4.x

```
ArtixInstallDir/artix/version/wsdl
```

### Artix 5.x

```
ArtixInstallDir/wsdl
```

In a production environment, the `locator.wsdl` can be in any location.

Artix post-3.x also includes a copy of the Artix 3.x `locator.wsdl` file. By default, this file is installed in:

### Artix 4.x

```
ArtixInstallDir/artix/version/wsdl/oldversion
```

### Artix 5.x

```
ArtixInstallDir/wsdl/oldversion
```

The Artix 4/5-C++ configuration file, `artix.cfg`, resolves which `locator.wsdl` contract to use by distinguishing the QName with which the locator service is called. The default `artix.cfg` file contains the following lines:

```
bus:qname_alias:locator_oldversion = "{http://ws.iona.com/locator}LocatorService";
bus:qname_alias:locator = "{http://ws.iona.com/2005/11/locator}LocatorService";
...
bus:initial_contract:url:locator_oldversion =
    "ArtixInstallDir/artix/version/wsdl/oldversion/locator.wsdl";
bus:initial_contract:url:locator = "ArtixInstallDir/artix/version/wsdl/locator.wsdl";
```

Thus, if consumer code requests a reference using the QName `{http://ws.iona.com/locator}LocatorService`, then any request for the locator's initial contract is directed to the 3.x version of `locator.wsdl` in the `wsdl/oldversion` directory.

By using the Artix 4/5-C++ version of the locator QName, `{http://ws.iona.com/2005/11/locator}LocatorService`, any request for the locator's initial contract is directed to the 4.x/5.x-C++ version of `locator.wsdl`.

## Configuration for Artix post-3.x locator service

To allow Artix 3.x and post-3.x consumers to connect to an Artix 4.1, 4.2, or 5.x/C++ locator service, add one new configuration entry to the locator service configuration scope, as described in [“Artix post-3.x locator setup for backward compatibility” on page 11](#).

## Locator WSDL operation names

The names of public operations in the Artix 4 and 5 C++ version of `locator.wsdl` have been changed, as described in [Table 1](#).

**Table 1:** *Operation names in Artix 3 and Artix 4/5 locator.wsdl*

Artix 3 locator.wsdl	Artix 4/5 C++ locator.wsdl	Notes
lookup_endpoint	lookupEndpoint	The Artix 3 version returns an Artix Reference. The Artix 4/5-C++ version returns a WS-Addressing type reference.
list_endpoints	listEndpoints	
	queryEndpoints	There is no Artix 3 equivalent operation.

## Migrating consumer code to Artix post-3.x

As described in [“Migrating from Previous Versions” on page 9](#), the Artix 4/5-C++ locator supports the use of unmodified Artix 3 consumers. This allows you to put your first migration efforts into upgrading your locators and services to Artix 4 or 5-C++. Once those tasks are complete, you can migrate your consumers as follows:

1. Edit your configuration files to make sure the `locator_client` plug-in is loaded in the configuration scope(s) used by your locator consumers. See [“Configuring C++ Consumers” on page 29](#).
2. If your code directly invokes any operations of the `locator.wsdl` contract, update the operation names as described in [“Locator WSDL operation names” on page 41](#).
3. For consumers in C++, simplify your consumer code as described below.

In Artix 3, the coding steps that every locator consumer had to take were the following:

- i. Invoke `IT_Bus::Bus::resolve_initial_reference()` on the locator's `QName`.
- ii. Using the returned reference, invoke `IT_Bus::ClientProxyBase()` to set up a proxy to the locator.
- iii. Using the proxy, invoke the locator's `lookup_endpoint` operation to get a reference to the target service.
- iv. Using the reference returned by the locator, invoke `ClientProxyBase()` to set up a proxy to the target service.

In Artix post-3-x, because the `locator_client` plug-in is doing most of the work, the coding steps are shortened to the following:

- i. Invoke `IT_Bus::Bus::resolve_initial_reference()` on the target service's `QName`.
- ii. Using the returned reference, invoke `IT_Bus::ClientProxyBase()` to set up a proxy to the target service.

**Note:** If your application invokes the `listEndpoints` or `queryEndpoints` operations of the locator service, then you must still create a proxy to the locator service. This is described in ["Querying a Locator Service" on page 34](#).

# Using the Locator from a Non-Artix Client

*The Artix locator service can be used by consumers generated by other SOA systems.*

## Implementing a .NET Client

.NET clients can use the locator to discover services, using the `Bus.Services.dll` library. The locator provides a number of methods for looking up services and managing service registration. The Artix .NET plug-in is Web Services Enhancements 2.0 (WSE 2.0) compliant. The helper classes included in the `Bus.Services` library simplify working with the locator by providing native .NET calls to access the locator and the endpoint references it produces.

## What you need before starting

Before starting to develop a client that uses the Artix locator you need:

- A means for contacting a deployed Artix locator. This can be one of the following:
  - ◆ An endpoint reference
  - ◆ An HTTP address
  - ◆ A local copy of the locator's contract
- A locally accessible copy of the WSDL contract that defines the service that you want the client to invoke upon.
- To install WSE 2.0 SP3 before starting an Artix .NET locator client.

## Demonstration code

The code examples in this section are taken from the locator demo's .NET client code. The .NET client makes a request on a service instance for which it does not have a current endpoint reference. The .NET client accesses the locator to get a reference to an active instance of the service on which it wants to make requests. The complete client code can be found in the following directory of your Artix installation:

```
InstallDir\samples\advanced\locator\dotnet\client
```

## Procedure

To develop a .NET client that uses the Artix locator, do the following:

1. Create a new project in Visual Studio.
2. Right-click the folder for your new project and select **Add Reference** from the pop-up menu.
3. Click **Browse** on **Add Reference** window.
4. In the file selection window, browse to your Artix installation and select the `Bus.Services.dll` from the `InstallDir\utils\.NET` directory.
5. Click **OK** to return to the Visual Studio editing area.
6. Right-click the folder for your new project and select **Add Web Reference** from the pop-up menu.
7. In the **Address:** field of the browser, enter the full path name of the contract for the service on which you are going to make requests.
8. Click **Add Reference** to return to the Visual Studio editing area.
9. Open the `.cs` file generated for the contract you imported.
10. Locate the class declaration for the service on which you intend to make requests. The class declaration looks similar to that shown in [Example 8](#).

### Example 8: .NET Service Proxy Class Declaration

```
public class SOAPService :  
    System.Web.Services.Protocols.SoapHttpClientProtocol {
```

11. Add a new C# class to your project.
12. Add the statement `using Bus.Services;` after the statement `using System;`.
13. Create a service proxy for the Artix locator by instantiating an instance of the `Bus.Services.Locator` class as shown in [Example 9](#).

### Example 9: Instantiating a Locator Proxy in .NET

```
Locator l = new Locator("http://localhost:8080");
```

The constructor's parameter is the HTTP address of a deployed locator. The `Locator` class also has two constructors that take an Artix reference or a WSDL contract for use with the Artix locator.

14. Create a `QName` representing the name of the service you wish to locate using an instance of the `System.Xml.XmlQualifiedName` class as shown in [Example 10](#).

### Example 10: Creating a .NET QName

```
XmlQualifiedName service = new XmlQualifiedName(  
    "HelloWorldService",  
    "http://www.iona.com/hello_world_soap_http"  
);
```

15. Invoke the `lookup_endpoint()` method on the locator proxy as shown in [Example 11](#).

**Example 11:** *Looking-up an Endpoint Reference.*

```
Reference ref = l.lookupEndpoint(service);
```

`lookupEndpoint()` takes the QName of the desired service as a parameter and returns an endpoint reference if an instance of the specified service is registered with the locator instance. Endpoint references are implemented in the `.NET Bus.Services.EndpointReferenceType` class.

16. Create a `.NET` proxy for the service on which you are going to make requests as you normally would.
17. Change the value of the proxy's `.Url` member to the SOAP address of the endpoint reference returned from the locator as shown in [Example 12](#).

**Example 12:** *Changing the URL of a .NET Service Proxy to Use an Endpoint Reference*

```
simpleService.Url = endpoint.Address.Value;
```

18. Make requests on the service as you would normally.

## Implementing an Axis Client

Because the Artix locator is a SOAP over HTTP service whose interface is defined by a WSDL contract, an Axis client can use it to locate deployed instances of a service. Using the Artix locator from an Axis client involves generating a proxy for the locator service and interpreting the returned endpoint reference.

### Axis version

The examples in this chapter were developed using Axis 1.3. They should work with Axis 1.4 as well.

### Procedure

To develop an Axis client that uses Artix locator, do the following:

1. Generate a WSDL file from a running locator instance.
2. Generate Axis stub code from the generated locator WSDL file as shown in [Example 13](#):

**Example 13:** *Generating Axis Stub Code for Locator*

```
Java org.apache.axis.wsdl.WSDL2Java locator.wsdl
```

3. Generate Axis stub code from the WSDL document for the service on which you want your client to invoke, as shown in [Example 14](#):

**Example 14:** *Generating Axis Stub Code for the Target Web Service*

```
Java org.apache.axis.wsdl.WSDL2Java simple_service.wsdl
```

**Note:** Axis only understands services that use SOAP over HTTP. If you are starting from the WSDL for an Artix service that supports other bindings and transports, you must make a copy of its WSDL document and remove references to any namespaces, bindings, and transports other than SOAP over HTTP. Then run the Axis WSDL2Java generator on your simplified copy of the WSDL document.

4. Retrieve a locator service endpoint as shown in [Example 15](#):

**Example 15:** *Retrieving a Locator Service Endpoint*

```
String tns = "http://ws.iona.com/2005/11/locator";
QName service = new QName(tns, "LocatorService");
String port = "LocatorServicePort";
java.lang.String url = get_soap_address("locator.wsdl",
    service, port);
java.net.URL endpoint = new java.net.URL(url);
```

5. Instantiate a locator proxy as shown in [Example 16](#):

**Example 16:** *Instantiating a Locator Proxy*

```
LocatorService_Service lssl = new
    LocatorService_ServiceLocator();
LocatorServiceBindingStub locProxy =
    (LocatorServiceBindingStub)lssl.getLocatorServiceP
    ort(endpoint);
```

6. Get a reference to a service using the locator proxy as shown in [Example 17](#).

**Example 17:** *Getting an Endpoint Reference*

```
QName servName = new
    QName("http://www.iona.com/FixedBinding",
    "SOAPHTTPService");
EndpointReferenceType serviceEpr =
    locProxy.lookupEndpoint(servName);
```

7. Get the address of the service from the returned endpoint reference as shown in [Example 18](#).

**Example 18:** *Getting the Service Address*

```
String servURL =
    serviceEpr.getAddress().get_value().toString();
serv_endpoint = new java.net.URL(servURL);
```

8. Create a proxy for the service and invoke on it as you normally would.
